Compositional Memory Management in the λ -calculus

Or: A Compositional Semantics for Explicit Naming

Sky Wilshaw, Graham Hutton

School of Computer Science, University of Nottingham

12th June 2025

let
$$x = 1 + 2$$
 in $\underbrace{print(x + x)}_{\text{scope of } x}$

let
$$x = 1 + 2$$
 in $\underbrace{print(x + x)}_{\text{scope of } x}$

With *explicit naming*, we use explicit operations to manipulate names:

bind x to 1 + 2 in print (read x + read x); free x

Names are first-class citizens:

bind x to 4 in x returns x, not 4

In explicit naming, names are like pointers

- *bind x to* 7 allocates memory to hold the value 7
- *read x* dereferences the pointer *x*
- *free x* deallocates the memory pointed to by *x*

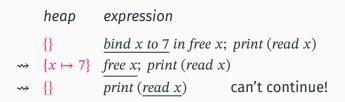

Important: The value bound to a name cannot change (so names are like 'immutable pointers')

Explicit naming is a fragment of manual memory management

We track bindings using a *heap*, mapping names to values The heap is updated during every computation step

	heap	expression	
	8	bind x to 7 in print	(read x); free x
>	$\{x \mapsto 7\}$	print (read x); free :	x
>	$\{x \mapsto 7\}$	print 7; free x	7 is printed
>	$\{x \mapsto 7\}$	free x	
>	{}		

What if we free x before reading from it?

Behaviour is very sensitive to order of evaluation

The heap is threaded through the computation, so the semantics is *non-compositional*

Currently, our evaluator is a partial function of type

 $Expr \rightarrow Heap \rightarrow Heap \times Value$

We can write this as

Expr \rightarrow *T* Value where *T* = Heap \rightarrow Heap \times (–)

Can we replace T with a better (more compositional) monad?

Currently, our evaluator is a partial function of type

 $Expr \rightarrow Heap \rightarrow Heap \times Value$

We can write this as

Expr \rightarrow *T* Value where *T* = Heap \rightarrow Heap \times (–)

Can we replace T with a better (more compositional) monad?

$$U = \underbrace{\text{Context}}_{\text{like a fixed heap}} \rightarrow \underbrace{(\text{Heap} \rightarrow \text{Heap})}_{\text{effect on the heap}} \times (-)$$

Crucially: The context isn't modified by heap effects, and effects are composed using their monoid structure.

This semantics is **equivalent** to the stateful semantics!

$$\operatorname{eff}_{\Gamma}(\operatorname{read} x)(H) = \begin{cases} H & \text{if } x \in \operatorname{dom} H \\ \uparrow & \text{otherwise} \end{cases}$$

$$\operatorname{eff}_{\Gamma}(\operatorname{free} x)(H) = \begin{cases} H' & \text{if } H = H', x \mapsto v \\ \uparrow & \text{otherwise} \end{cases}$$

$$\operatorname{eff}_{\Gamma}(e_1; e_2) = \operatorname{eff}_{\Gamma}(e_2) \circ \operatorname{eff}_{\Gamma}(e_1)$$

The same context Γ is used for both e_1 and e_2

- In *explicit naming*, we manipulate names manually using explicit operations
- Explicit naming can be viewed as a fragment of manual memory management
- The evaluator can be thought of as a monadic function $\operatorname{Expr} \to T$ Value
- By replacing *T* with a 'better' monad *U* we reduce dependence on state
- Paper coming soon!

Thank you!

$$H : e \Downarrow H' : v \iff$$
